Abstract No: 11616

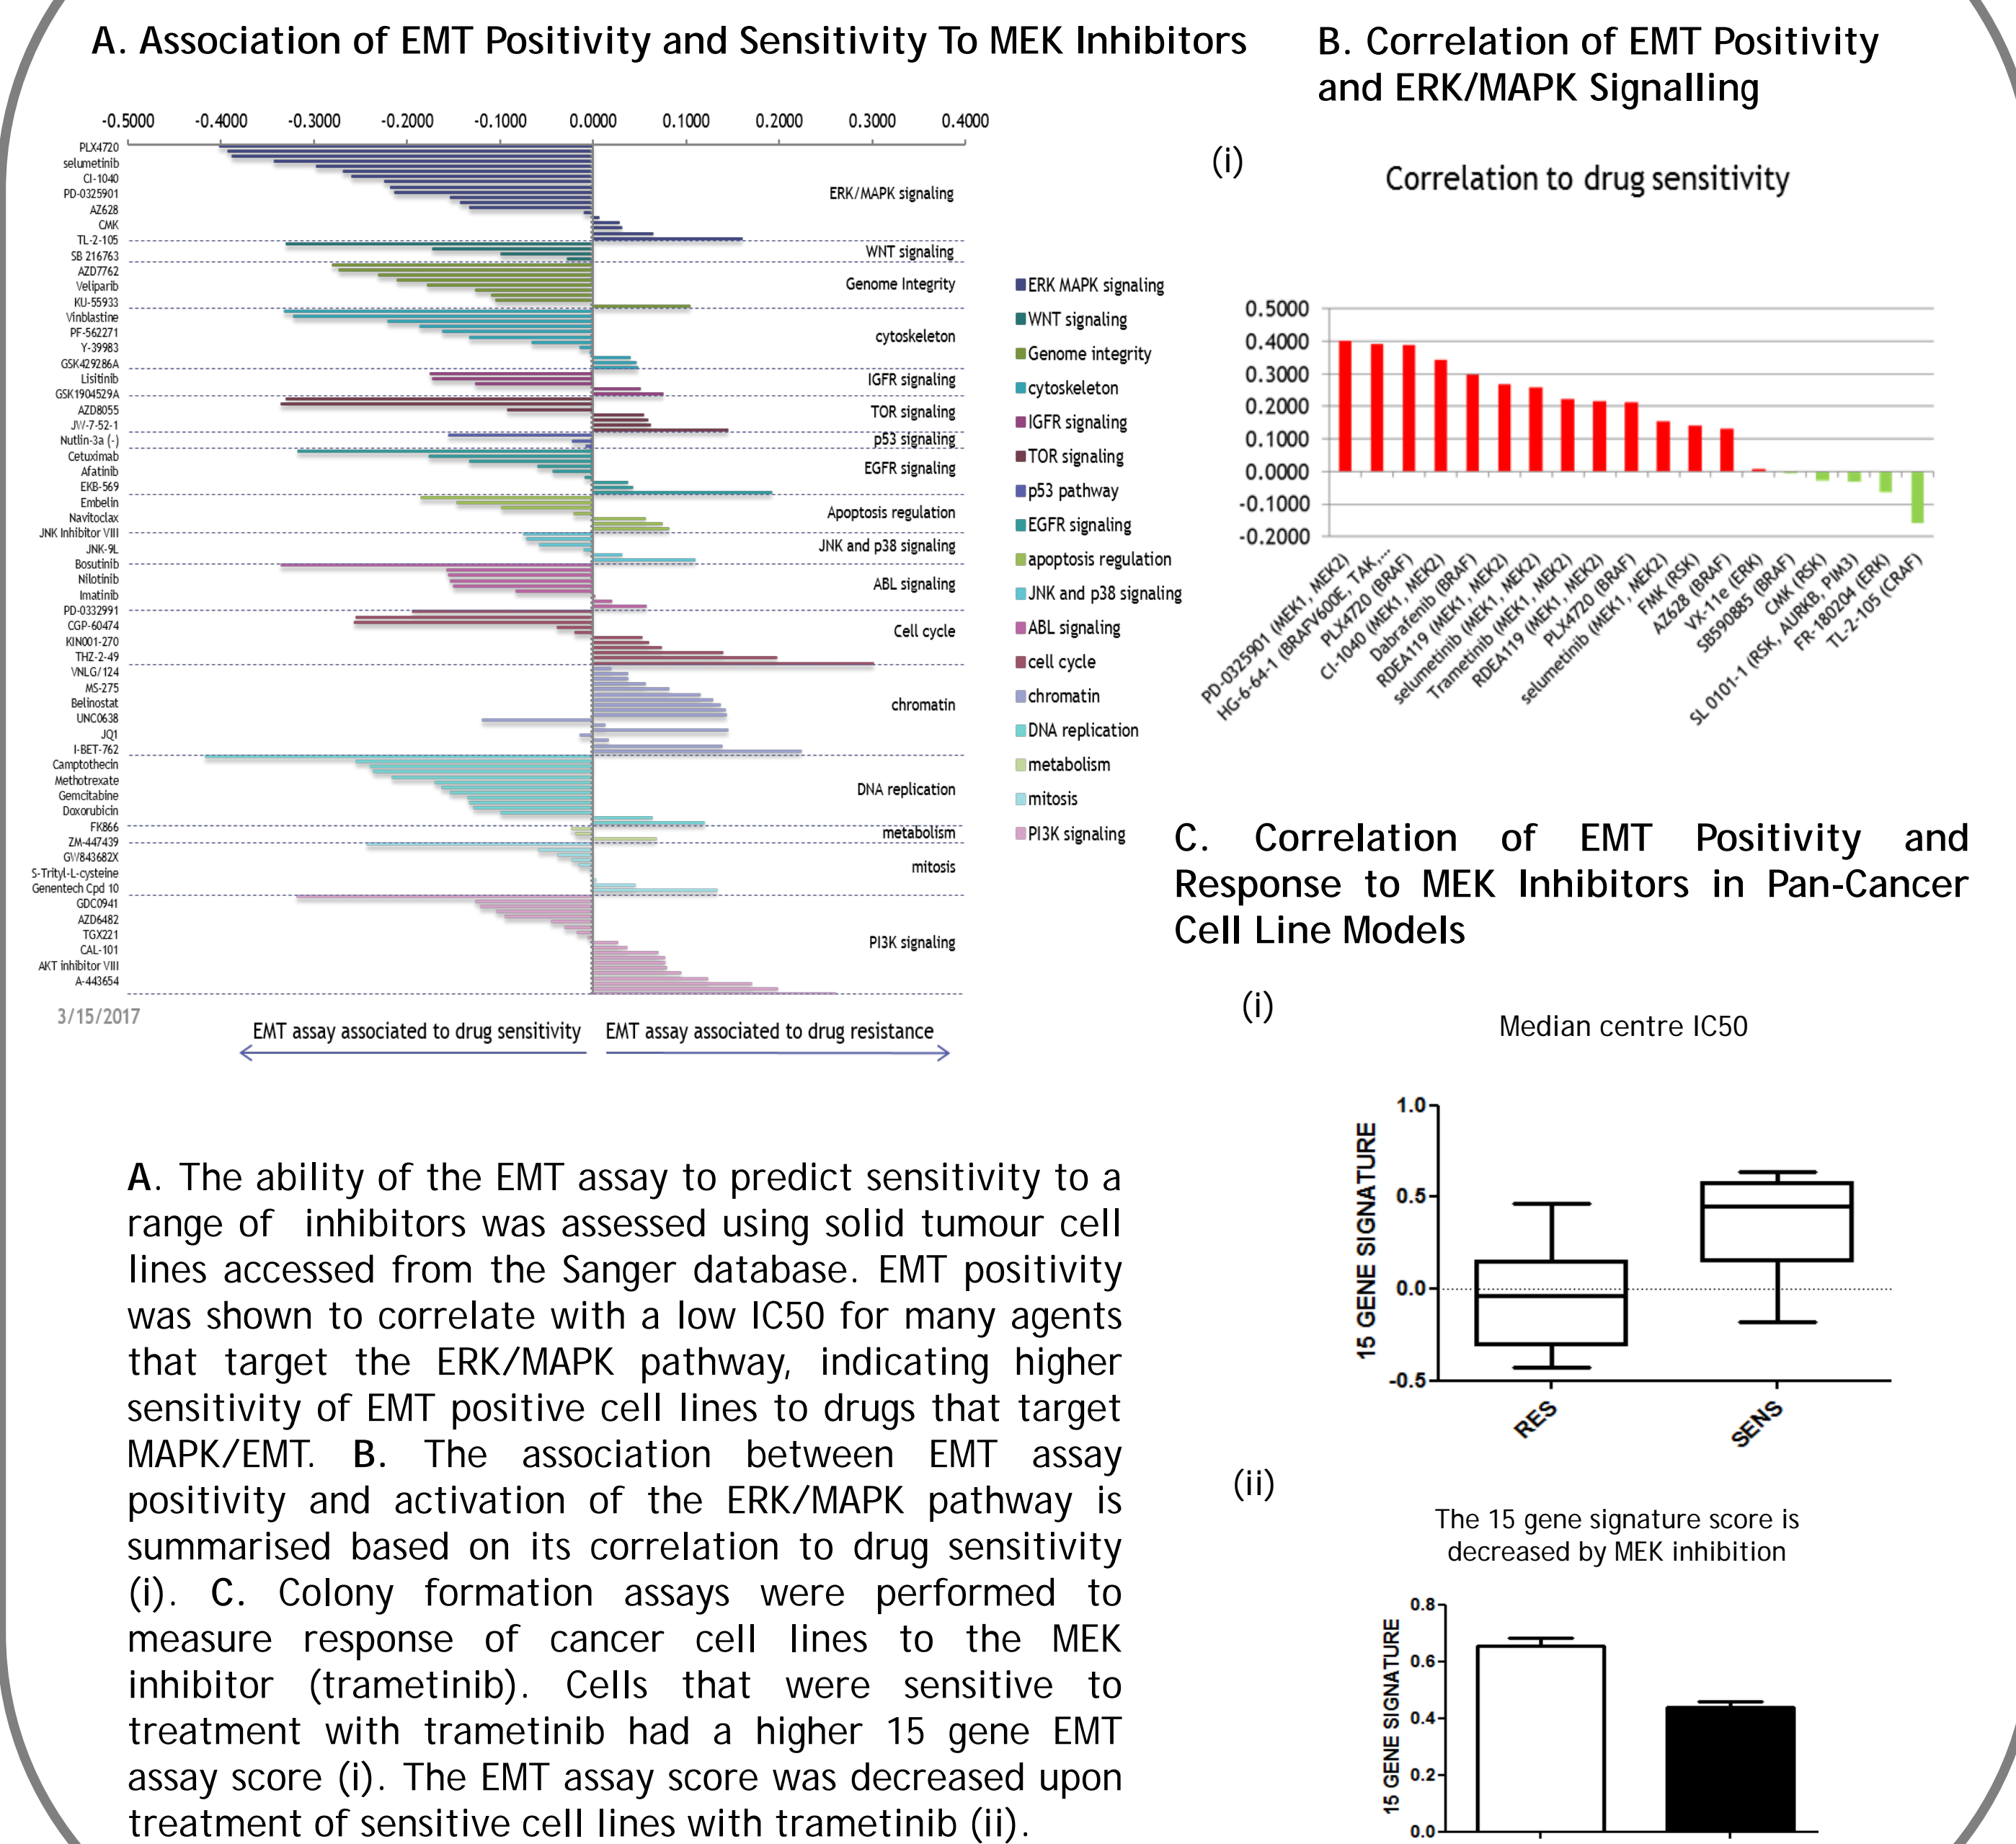

Background

- Unsupervised hierarchical clustering of gene expression data from 265 high grade serous ovarian cancer (HGSOC) tumors identified 3 molecular subgroups.
- These were characterised by upregulation of angiogenesis (Angio subgroup), immune (Immune subgroup) and both angiogenesis and immune (Angioimmune subgroup) genes, respectively.
- Further characterisation of the Angioimmune subgroup reveals it to be driven by MAPK pathway activation and is associated with an EMT (Epithelial to Mesenchymal Transition) like phenotype.
- The aim of this study was to develop a gene signature which could detect the MAPK/EMT subgroup across multiple cancer types.
- Using our datasets and publically available gene expression datasets we have demonstrated that the MAPK/EMT subgroup (as defined by 'EMT assay') exists in other cancer types and is associated with poor prognosis.
- A positive result for the EMT assay is associated with higher sensitivity to drugs which target components of the MAPK and EMT pathways.

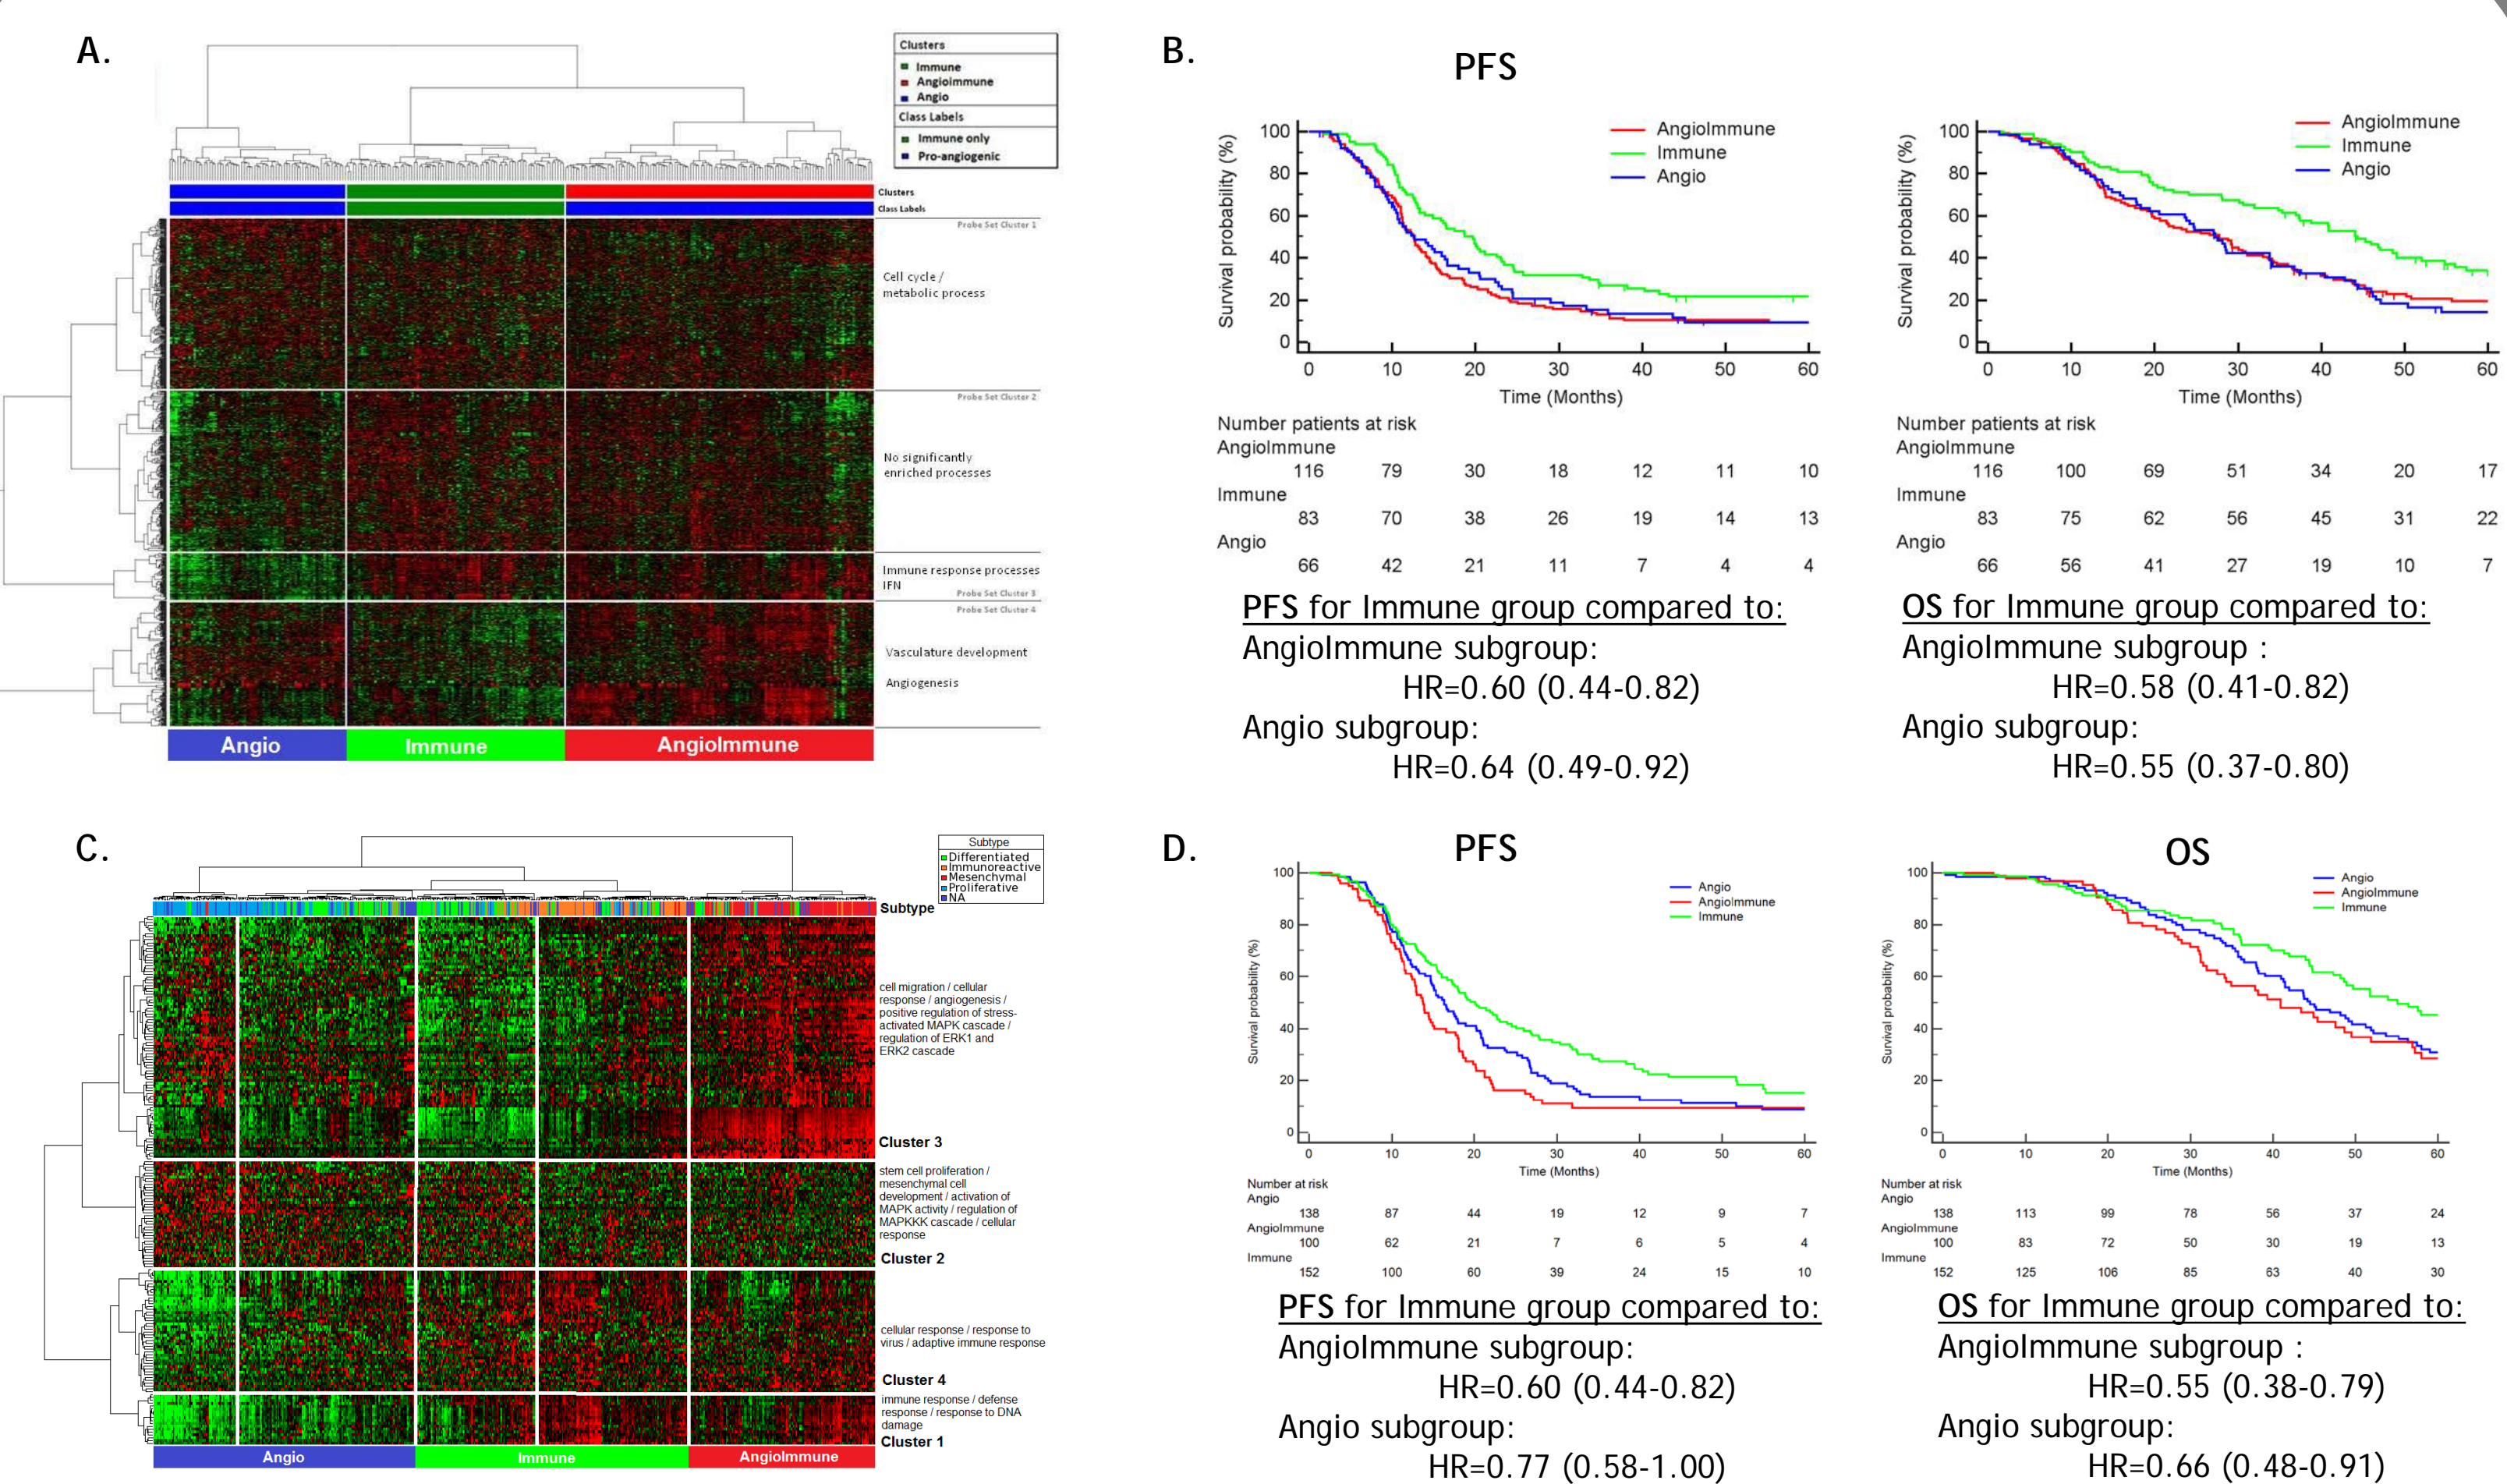

Development of Pan-Cancer gene expression Signature for MAPK/EMT That is Predictive of Poor Prognosis

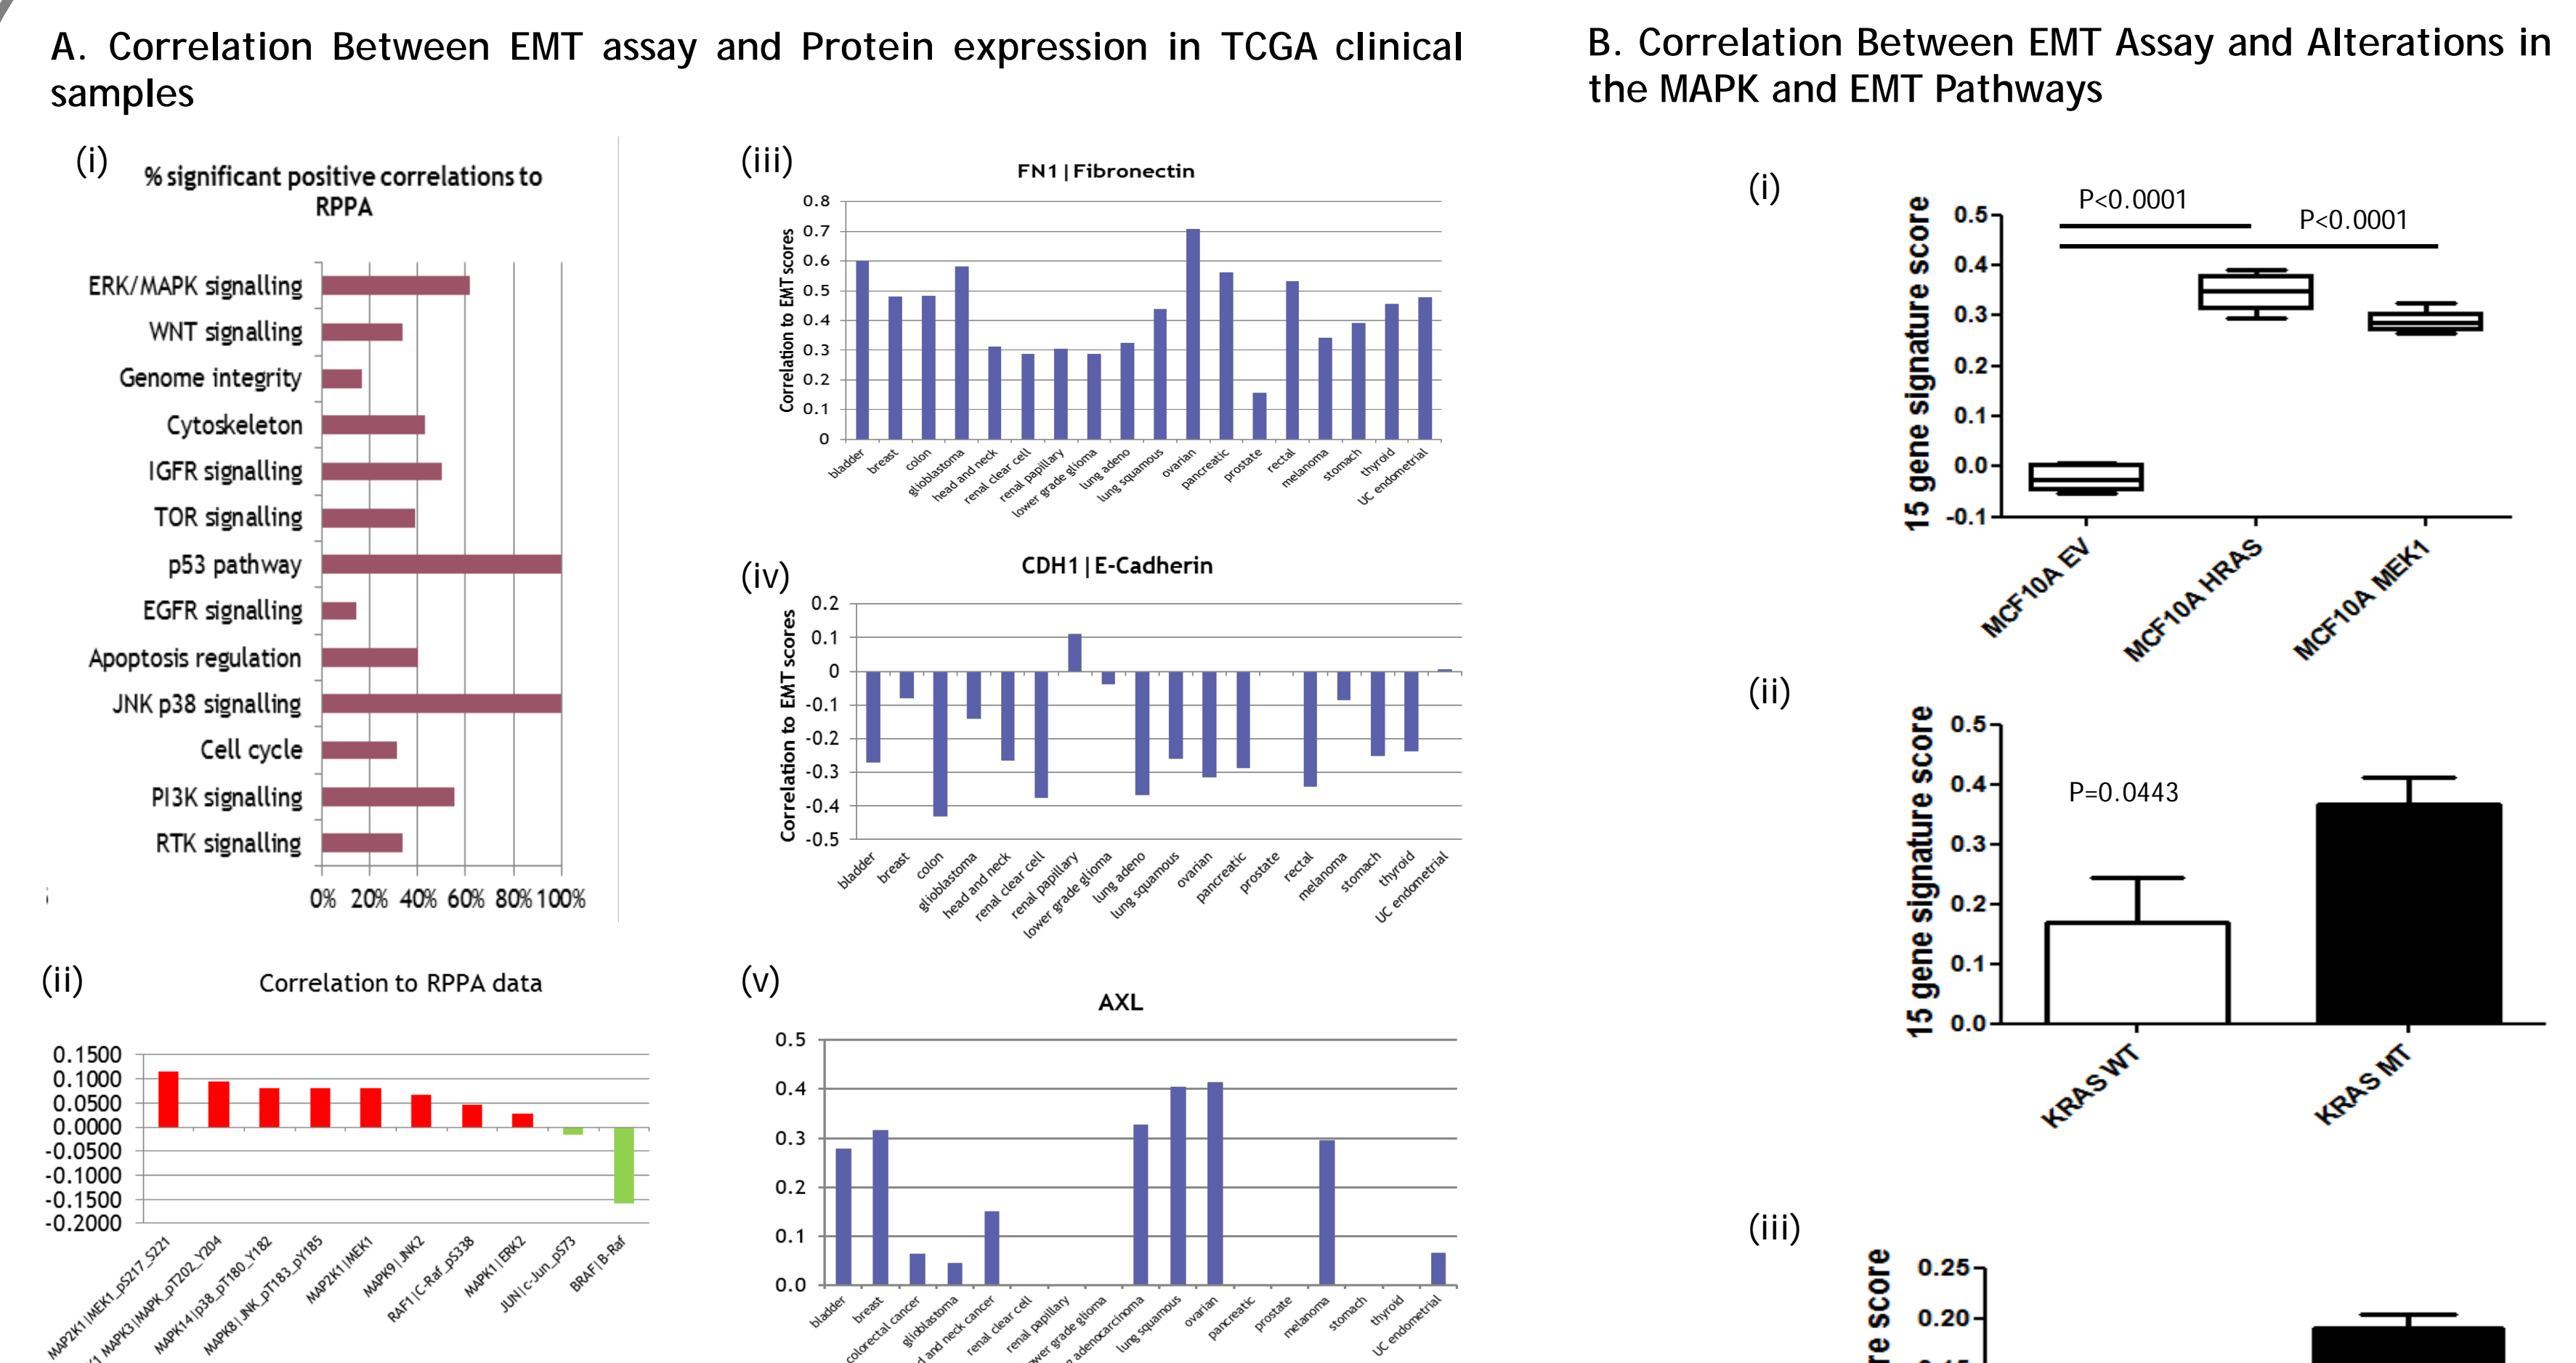

Correlation of EMT Assay with Drug Response Data

Identification of Molecular Subgroups of High Grade Serous Ovarian Cancer

Correlation of EMT Assay with Protein Expression Data

Conclusions

- A 15 gene signature has been developed from formalin fixed paraffin embedded samples to detect a molecular subgroup driven by MAPK/EMT signalling across multiple diseases.
- This assay predicts sensitivity to MEK inhibitors in pre-clinical model systems.
- Further work aims to validate the EMT assay in clinical samples from patients treated with a MEK or EMT inhibitor.
- This assay may be helpful for clinical trial enrichment to select patients that are likely to benefit from MAPK or EMT targeted therapies.
